Macronutrients or 'macros' are the three main nutrient groups your body can't live without: carbohydrates, fats and protein. So many diets focus on calorie counting, but not all calories are created equal: your body doesn't process 20 calories of kale and 20 calories of chocolate in the same way because of their different macro breakdowns. Macro counting is all about balance. By eating the right ratio of carbohydrates, fats and protein, you can lose weight and build muscle in a healthy, sustainable way without avoiding the foods you love. This flexible approach to dieting encourages you to make smart food choices that guarantee results. The Macro Method will tell you everything you need to know about counting macros, including the latest research about how the diet works and its nutritional benefits. The 21-day plan will help you ditch the calorie counting for good, with more than 40 simple recipes to tempt you.

Dietary reference values for energy Scientific Advisory Committee on Nutrition,2012-05-02 Dietary reference values (DRVs) for energy are based on estimating the total energy expenditure (TEE) for groups of people. TEE provides a measure of the energy requirement at energy balance i.e. when energy intake matches energy expenditure. The methodology to measure TEE - the doubly labelled water (DLW) method - has advanced and as a result, the evidence base on TEE in a wide variety of population groups has expanded considerably. With the high levels of

overweight and obesity currently seen in the UK and the wealth of new data now available, it was considered timely for the Scientific Advisory Committee on Nutrition (SACN) to review recommendations for the UK population. This report details the evidence and approaches SACN have considered in order to update the DRVs for energy. SACN chose a prescriptive approach to estimating energy reference values; suitable reference body weight ranges consistent with long-term good health were used to calculate energy reference values. Thus, basal metabolic rate (BMR) values were predicted using healthy reference body weights. Using this approach, if overweight groups consume the amount of energy recommended for healthy weight groups, they are likely to lose weight, whereas underweight sections of the population should gain weight towards the healthy body weight range. SACN has derived new energy reference values. For most population groups, except for infants and young children, the values have increased. DRVs should be used to assess the energy requirements for large groups of people and populations, but should not be applied to individuals due to the large variation in physical activity and energy expenditure observed between people.
