Data Architecture: A Primer for the Data Scientist W.H. Inmon, Daniel Linstedt, Mary Levins, 2019-04-30 Over the past 5 years, the concept of big data has matured, data science has grown exponentially, and data architecture has become a standard part of organizational decision-making. Throughout all this change, the basic principles that shape the architecture of data have remained the same. There remains a need for people to take a look at the bigger picture and to understand where their data fit into the grand scheme of things. *Data Architecture: A Primer for the Data Scientist*, Second Edition addresses the larger architectural picture of how big data fits within the existing information infrastructure or data warehousing systems. This is an essential topic not only for data scientists, analysts, and managers but also for researchers and engineers who increasingly need to deal with large and complex sets of data. Until data are gathered and can be placed into an existing framework or architecture, they cannot be used to their full potential. Drawing upon years of practical experience and using numerous examples and case studies from across various industries, the authors seek to explain this larger picture into which big data fits, giving data scientists the necessary context for how pieces of the puzzle should fit together. New case studies include expanded coverage of textual management and analytics New chapters on visualization and big data Discussion of new

visualizations of the end-state architecture

Structured Search for Big Data Mikhail Gilula, 2015-08-26 The WWW era made billions of people dramatically dependent on the progress of data technologies, out of which Internet search and Big Data are arguably the most notable. Structured Search paradigm

connects them via a fundamental concept of key-objects evolving out of keywords as the units of search. The key-object data model and KeySQL revamp the data independence principle making it applicable for Big Data and complement NoSQL with full-blown structured querying functionality. The ultimate goal is extracting Big Information from the Big Data. As a Big Data Consultant, Mikhail Gilula combines academic background with 20 years of industry experience in the database and data warehousing technologies working as a Sr. Data Architect for Teradata, Alcatel-Lucent, and PayPal, among others. He has authored three books, including *The Set Model for Database and Information Systems* and holds four US Patents in Structured Search and Data Integration. Conceptualizes structured search as a technology for querying multiple data sources in an independent and scalable manner. Explains how NoSQL and KeySQL complement each other and serve different needs with respect to big data Shows the place of structured search in the internet evolution and describes its implementations including the real-time structured internet search

their data and mature their information infrastructure, based on these principles: Data is an asset with unique properties; The value of data can be and should be expressed in economic terms; Managing data means managing the quality of data; It takes metadata to manage data; It takes planning to manage data; Data management is cross-functional and requires a range of skills and expertise; Data management requires an enterprise perspective; Data management must account for a range of perspectives; Data management is data lifecycle management; Different types of data have different lifecycle requirements; Managing data includes managing risks associated with data; Data management requirements must drive information technology decisions; Effective data management requires leadership commitment.

Scalable Big Data Architecture Bahaaldine Azarmi, 2015-12-31 This book highlights the different types of data architecture and illustrates the many possibilities hidden behind the term Big Data, from the usage of No-SQL databases to the deployment of stream analytics architecture, machine learning, and governance. Scalable Big Data Architecture covers real-world, concrete industry use cases that leverage complex distributed applications, which involve web applications, RESTful API, and high throughput of large amount of data stored in highly scalable No-SQL data stores such as Couchbase and Elasticsearch. This book demonstrates how data processing can be done at scale from the usage of NoSQL datastores to the combination of Big Data distribution. When the data processing is too complex and involves different processing topology like long running jobs, stream processing, multiple data sources correlation, and machine learning, it's often necessary to delegate the load to Hadoop or Spark and use the No-SQL to serve processed

data in real time. This book shows you how to choose a relevant combination of big data technologies available within the Hadoop ecosystem. It focuses on processing long jobs, architecture, stream data patterns, log analysis, and real time analytics. Every pattern is illustrated with practical examples, which use the different open source projects such as Logstash, Spark, Kafka, and so on. Traditional data infrastructures are built for digesting and rendering data synthesis and analytics from large amount of data. This book helps you to understand why you should consider using machine learning algorithms early on in the project, before being overwhelmed by constraints imposed by dealing with the high throughput of Big data. Scalable Big Data Architecture is for developers, data architects, and data scientists looking for a better understanding of how to choose the most relevant pattern for a Big Data project and which tools to integrate into that pattern.

Database Architecture Design – Memory to Storage using DB2 Lawrence

Dunn, 2016-04-14 It continues to amaze me on the number of corporations running data-based applications on DB2 who view it as a black-box that simply houses their application data. This disconnect with the importance of properly designed and more importantly...configured...data bases leads to application error, lowered customer satisfaction, drastically decreased potential being proactive with KPI's and increased hardware and support costs. This disconnect is so prevalent, that many organizations assume that the solution to a badly performing database is adding a score of new indexes, buying more memory or worse going through a massive conversion/upgrade effort with a new product. Capital expenditure on additional memory and storage for a database that simply needs to be properly configured for its' workload is something that I see various

companies do every year and it's a massive waste of shareholder equity. In a previous life, I was responsible for capacity planning with Procter & Gamble's technical infrastructure. Following the Pareto Principle (i.e., 80 /20 rule), the first thing that I did was identify which portion of the infrastructure was responsible for the highest costs in support, licensing and new expenditures. Three IBM 3090 mainframes jumped out with the highest costs so I initially placed my focus there. Looking at daily workloads of each environment what became apparent was that the utilization between each machine ran a little over 40%. This was a massive waste of resources. So I simply rebalanced the workload, dividing processing between two machines and eliminating the third. This simple act of effectively spreading workload utilization saved P&G \$2M/year. The workload within a DB2 database can also be effectively spread with an effective buffer pool and storage strategy. This will drastically improve overall performance, eliminating the need to acquire additional memory and lowering support costs. I've been in numerous pre-sales situations where a client will sign a contract to purchase a data based application and as the ink is drying they will then ask architecture questions that they should have addressed beforehand: · What type of DB2 license should we buy? · How much memory will we need? · How much storage? · What kind of storage? · How many LUNs will we need to configure? · How many CPU's will we need? These are all very relevant questions that should be addressed...before...making the decision to purchase a shiny new data based application. However, in my experience the key after the fact question that is rarely asked is, "What type of performance should I expect?" In my experience performance is seldom discussed during project startup, but it is...always...brought up once the application is in production.

The issue as I stated earlier, is that many technical professionals view DB2 as a black-box in that they are only concerned with...space. With this fixated view they look at the potential size of the database to figure out how much storage to purchase. Then the storage size is used to guestimate the amount of memory and CPU that should be required. The assumption is made that adequately estimating hardware based on database size will also equate into having adequate performance. This is a woefully inadequate assumption that will lead to subpar performance in your production environment. This white paper will illustrate via a case study the benefits of completing a database architecture design as one of the first project deliverables that contains the database configuration parameters, bufferpool design, tablespace design, LUN design, and device/file design. This will ensure optimal database performance and low capital expenditures for your project.
